Performance Metrics Breakdown

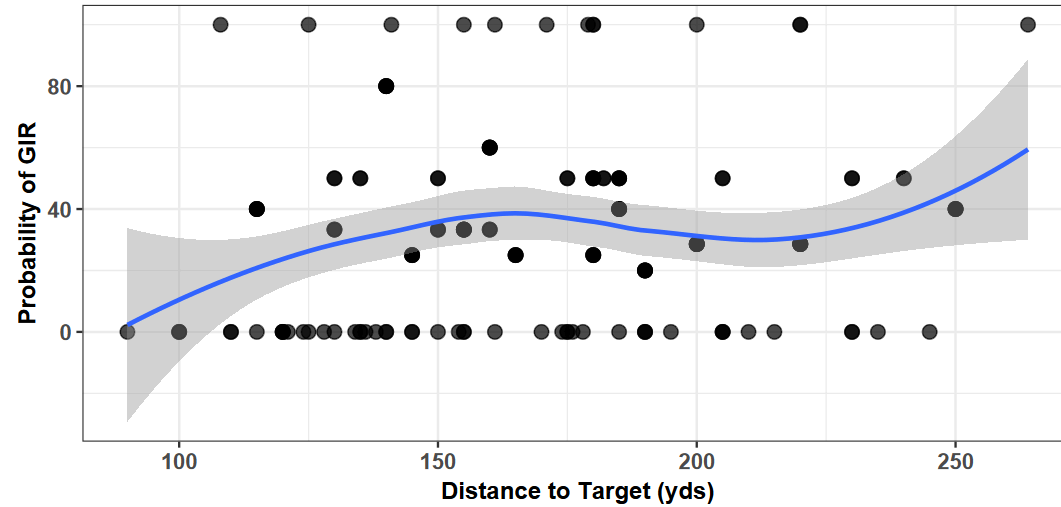

GIR %, FIR %, Scramble %, Penalties, and scoring relationships

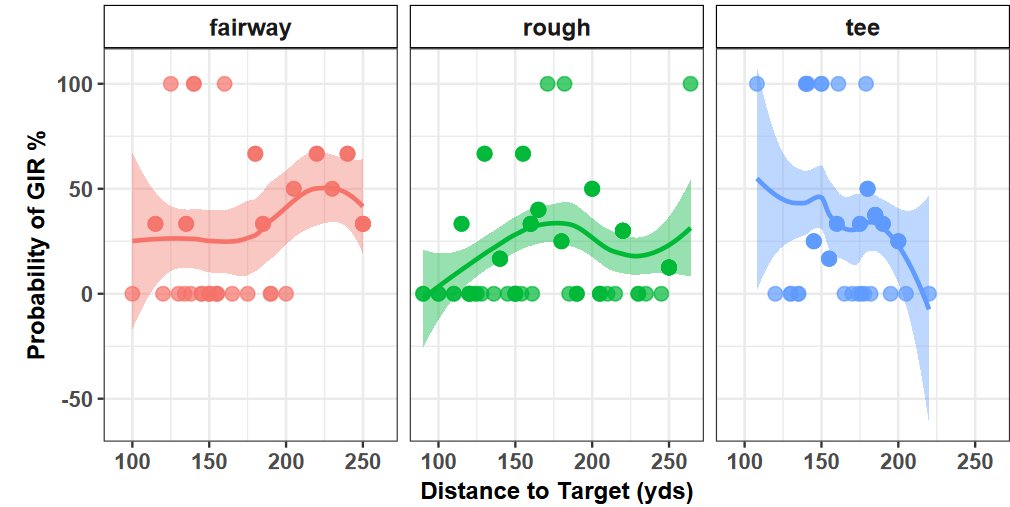

Approach Performance Diagnostics

Distance-based GIR probability, lie-type effects, and Par 3 performance

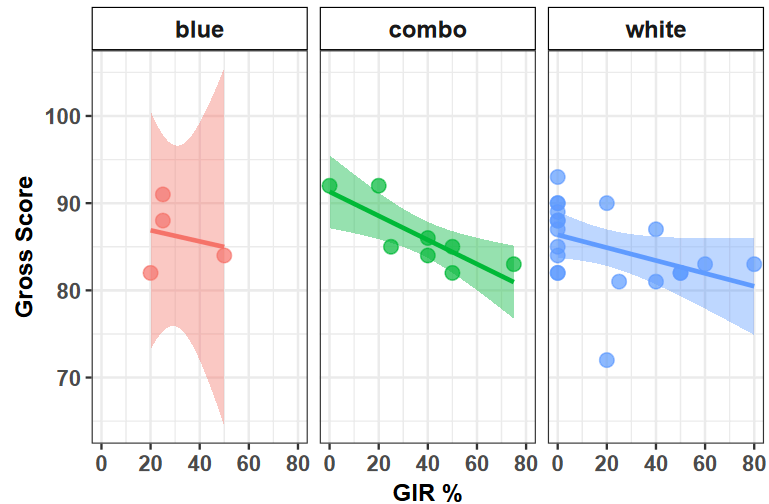

Approach Distance vs GIR Probability

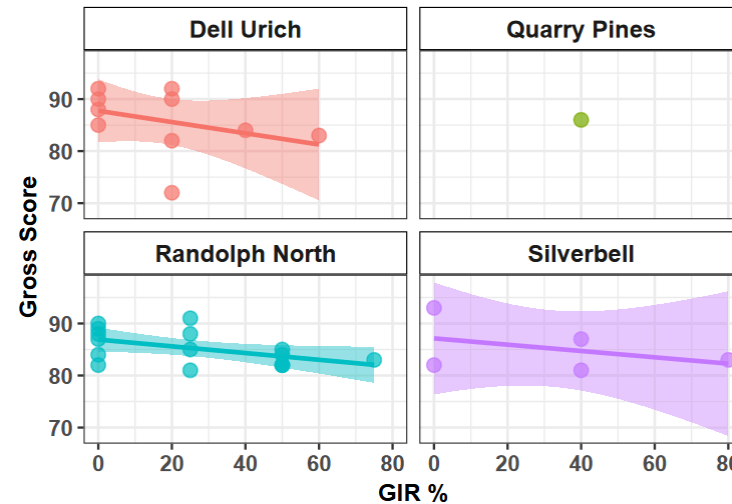

Approach GIR Probability vs Distance (by Lie)

Gross Score vs Par-3 GIR % by Tee Selection

Gross Score vs Par-3 GIR % by Course

Interpretation:

Distance drives GIR probability, with poor lies pulling the probability curve down because of spin and ball height loss

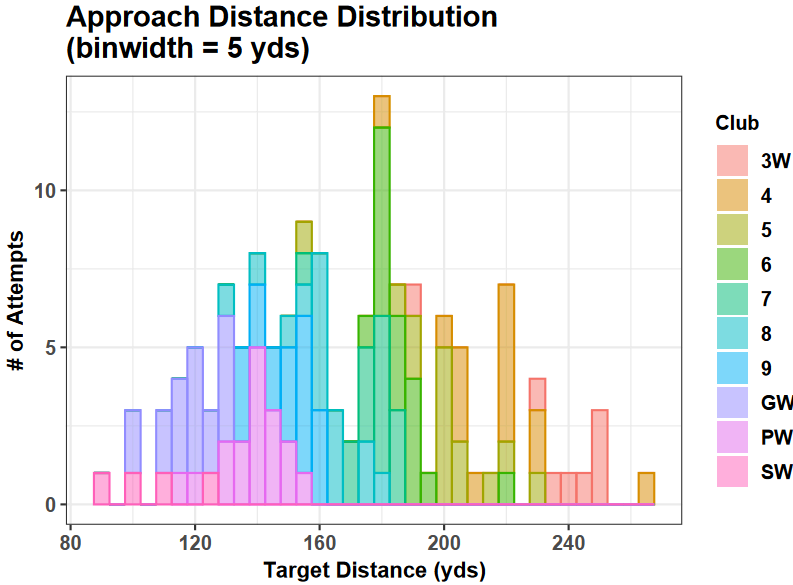

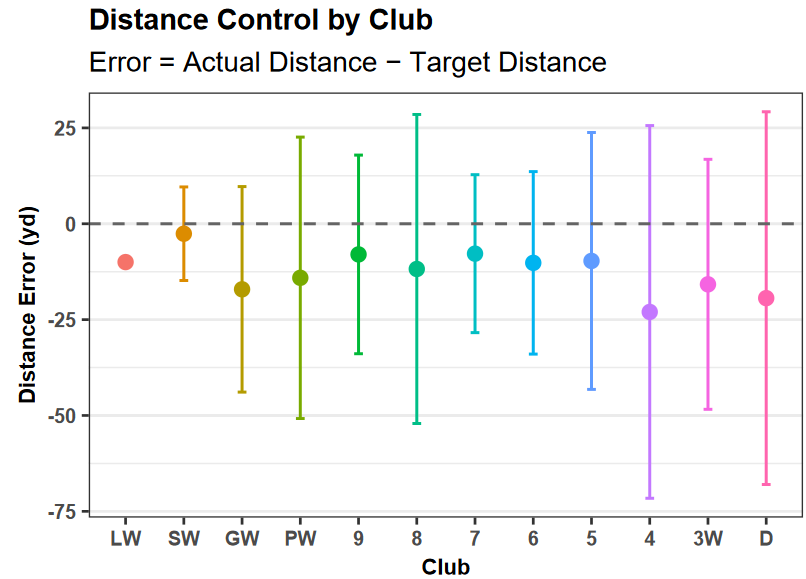

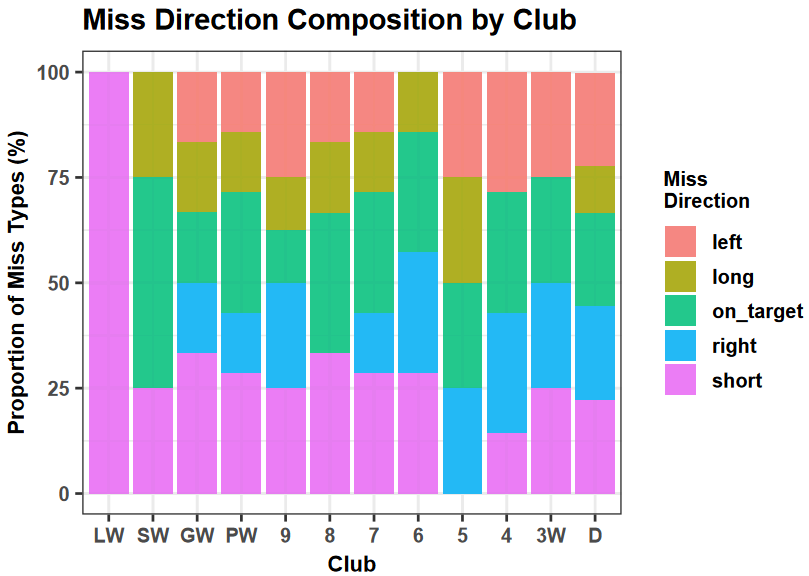

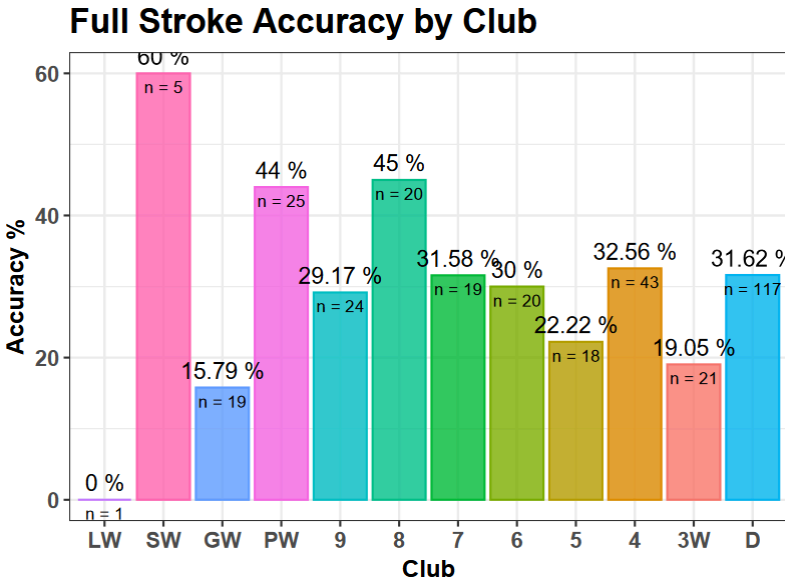

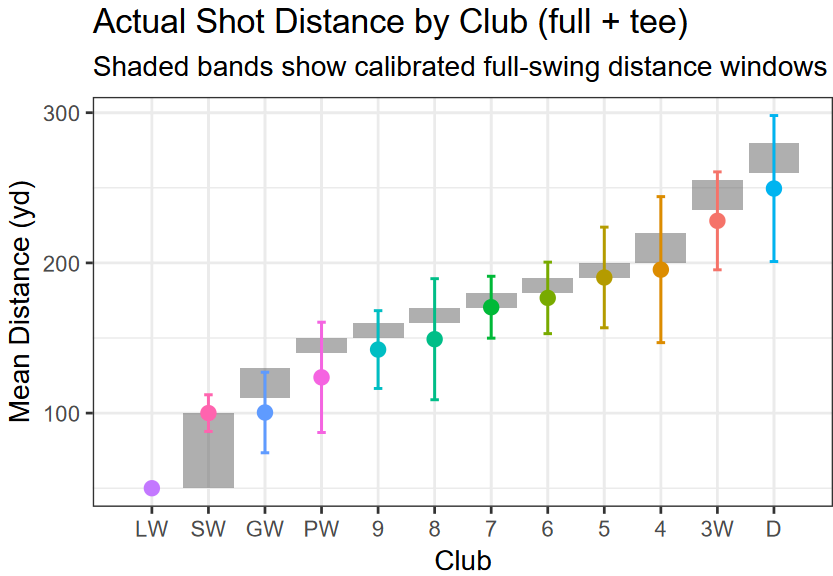

Long irons are strong-- when used from the fairway, they pull the probability curve up

Opportunities to improve from the fairway or off the tee at ~ 155 - 175 yards

Accounting for lie type, Par 3's highlight true iron skill and also reveal stability

Club-Level Performance Diagnostics

Distance windows, accuracy, miss-direction, approach patterns, and distance control

Interpretation:

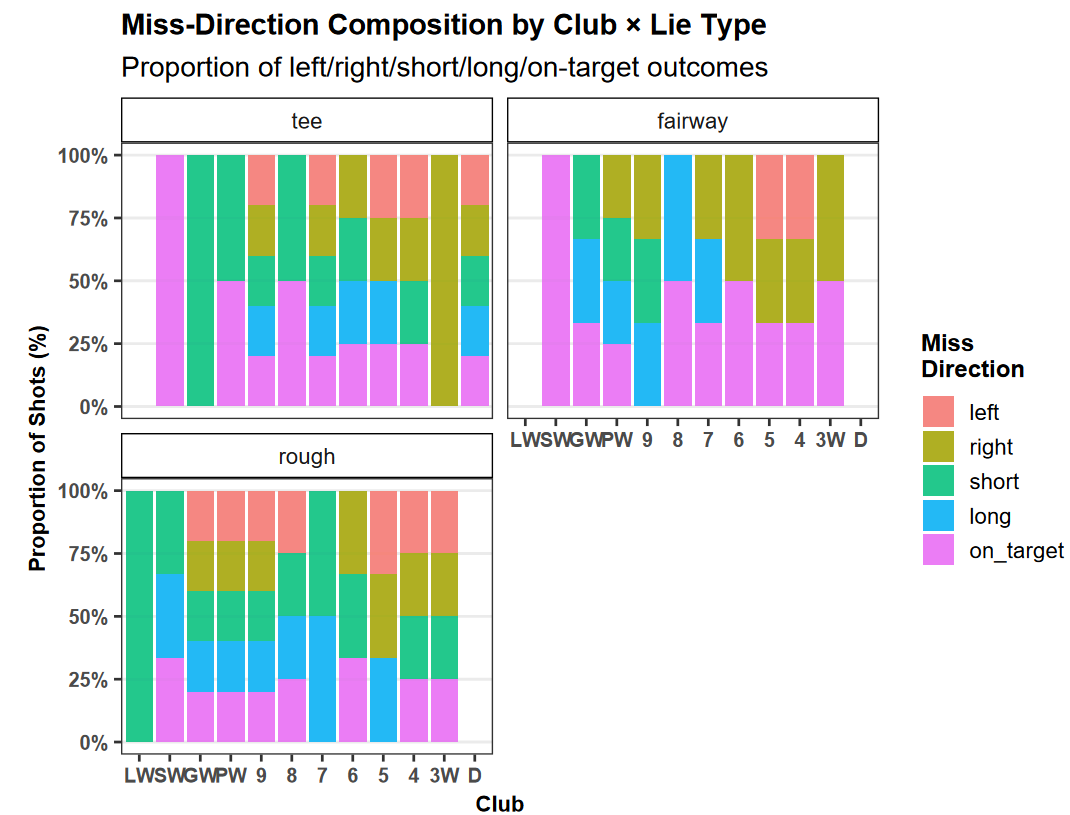

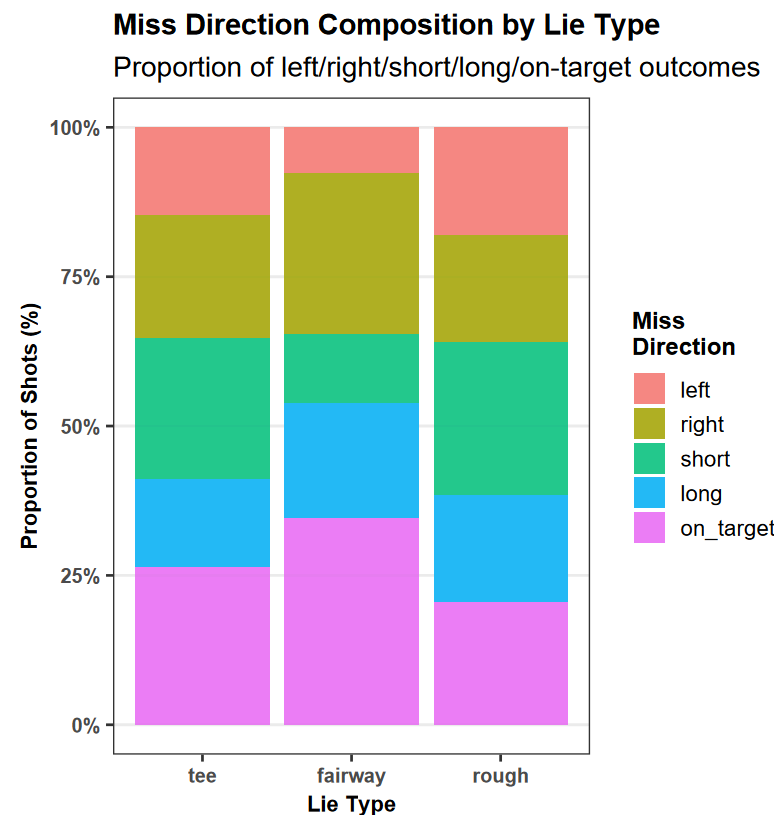

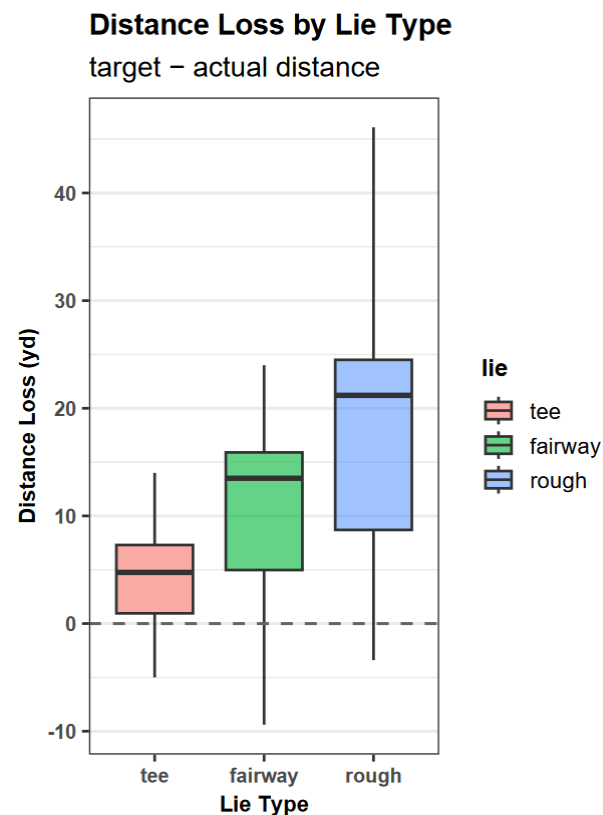

Club-level performance shows how distance windows, accuracy, and miss-direction patterns contribute to approach outcomes

Realistic, uniform, slight underperformance with most clubs: slightly shorter distances than calibrated distances

Mid-to-long irons are strong, with tighter variance, more accuracy, and less distance loss than wedges, which tend to miss long

Lie-Type Performance Diagnostics

Distance loss, directional tendencies, and lie-specific miss patterns

Interpretation:

Lie type strongly affects both distance loss and directional misses: less accuracy from the rough, with more frequent short- and left- misses (clubface/ball/ground contact variability)

Fairway is roughly equivalent to the tee in terms of distance lost, with more variation, more long misses (especially with wedges-- thin, bladed shots) and more right- misses
